STM32F746xx MCUs, can be adapted to any STM32 microcontroller. Digital Signal Processing (DSP) is the mathematical manipulation and processing of signals. Signals to be processed come in various physical formats that include audio, video or any analog signal that carries information, such as the output signal of a microphone.

When a STM32 device I/O pin is configured as input, one of three options must be selected: • Input with internal pull-up. Pull-up resistors are used in STM32 devices to ensure a well-defined logical level in case of floating input signal. Depending on application requirements, an external pull-up can be used instead.

The digital MEMS microphone is a sensor that convert acoustic pressure waves into a digital signal. The STM32 MCUs and MPUs acquire digital data from the microphone(s) through particular peripherals to be processed and transformed into data standard for audio. The audio data is then handled by the microcontroller according to the targeted audio

The STM32-DVM-MTR2K is specifically built for the MTR2000 and is not compatible with other repeaters. For the MSF5000, I strongly recommend the STM32-DVM from Scott Zimmerman, N3XCC at Repeater Builder. It is a more generic implementation that can be adapted to nearly any radio.

Analogue-to-Digital Converter is a system that converts an analog signal into a digital signal. STM32 series MCU has 1 to 3 ADCs, while STM32F103RCT6 has three. All these ADC are independent. The 12-bit ADC has up to 18 multiplexed channels allowing it to measure signals from 16 external and two internal sources.

With STM32 it doesn't. Averaging is a real bad way, and has nothing to do with good Design. Before averaging, the core Value must be stable, and the datasheet says +-2 Digit at 12Bit And don'T get this +-2 Digits only with STM32!! With an real 12BIT ADC, it isn't any problem, or an XMEGA
